Since the client already has all the necessary information, it only needs to make an HTTP POST request, # The server receives the POST request, and sends the file back to the client with the latest version of it. # The client receives the file and updates its internal copy of the file. #... What would be a security risk in a similar system? A: Yes, it does make sense to have it in this way. The reason is that if the data is encrypted (and that's the case in your example) the attacker cannot predict how the data will be encrypted. Therefore he cannot implement a targeted attack. If the data would be plain text instead, the attacker could implement a targeted attack, by looking for the plaintext data in the headers of the ciphertext. You could of course apply a form of obfuscation which makes it harder to spot the plaintext data. In that case you should still accept a targeted attack, but since the attacker will not be able to predict how the data will be encrypted, it will be much harder for him to implement a targeted attack. Also note that it's not always possible to hide the plaintext data without implementing some form of obfuscation. For example: If you encrypt a password, the encrypted data is usually stored as plain text in the database, so it can be stored there with just the knowledge of the encrypting and decrypting algorithms and the secret key. Edit: On the other hand, a targeted attack is always a possibility. When designing a network protocol, one has to make sure that the most important parts of it cannot be easily used in a targeted attack. Tag Archives: imf Many are upset that even with all of the rich bailouts, the U.S. is still not running an overall surplus. I don't think that is an appropriate place to focus your anger. To quote Mr. Bogle, "Bad money is still better than no money." The Fed has taken a big step in rectifying the problem of bad money by continuing to be a government lender of last resort. It is the right course of action because there is only one place where the United States could ever get a reserve currency – and that's through the issuance of its own currency. There is no escaping the fact that money is an instrument of exchange. Fiat money is based on the work of the private sector, not the government. The Fed will not be printing money forever. 82157476af
